**Remote Install** is a built-in tool that facilitates *Host* deployment across multiple stand-alone or domain remote PCs. You can use the tool to install, uninstall, start, stop and update a remote Host.

## How to use Remote Install tool

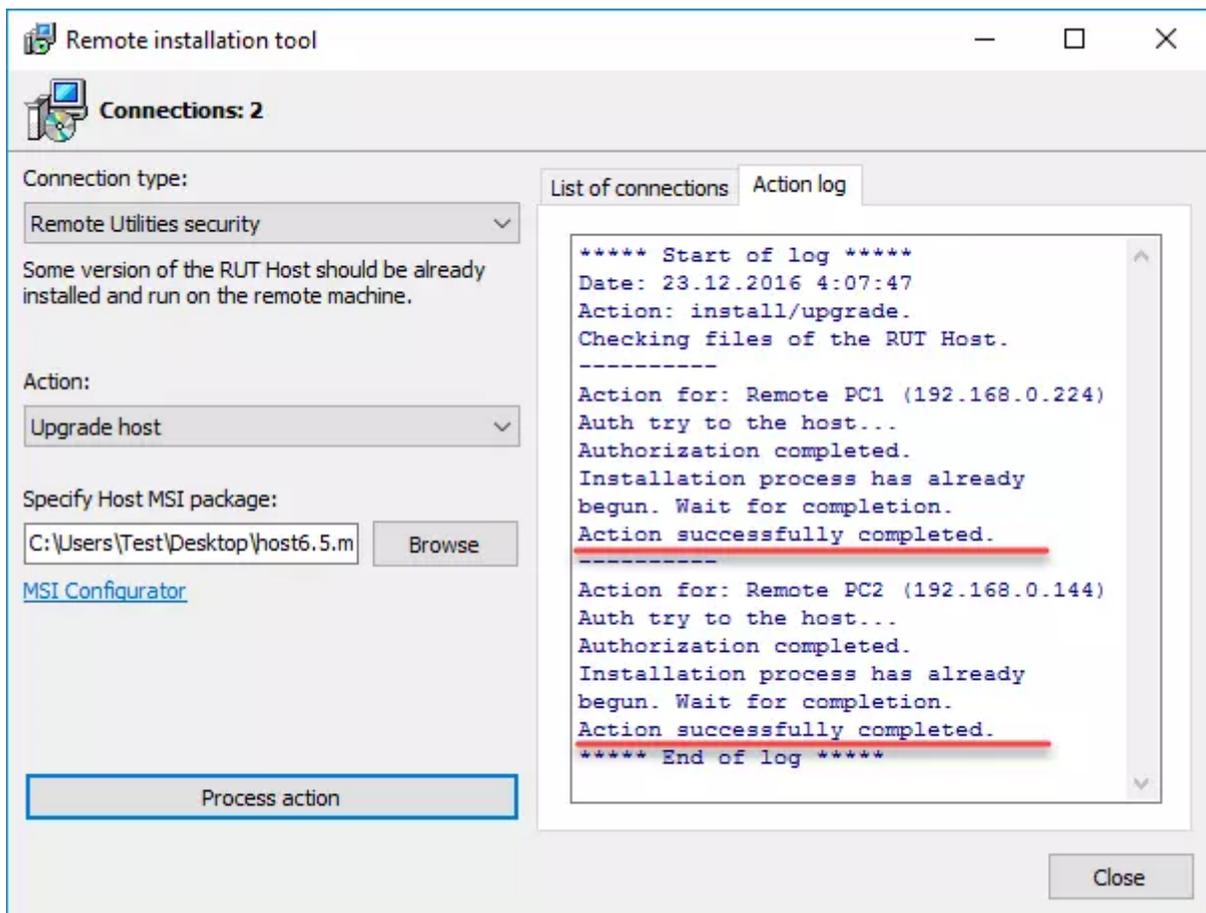

1. In the Viewer *address book* select a connection (or multiple connections) that you want to process using the Remote Install tool.
2. Select the **Tools** tab and click **Remote Install** on the toolbar.

3. A **Remote Install Tool** window will open. Select a desired **Connection type** and **Action**, and specify a path to the Host package by clicking **Browse**. See below for more information on these options.
4. Make sure the remote PCs that you want to apply the action to are selected on the **List of connections** tab:

5. Click **Process action**. The action progress will be displayed on the **Action log** tab:

## Connection type

Select how you want to connect to the remote PC:

- **Windows NT security** Connect to a remote computer using `admin$ share`. You must have local administrator rights on the remote PC. A typical example of using this option is "push-installing" the Host to a remote computer across your network.
- **Remote Utilities security** Connect to a remote computer using Remote Utilities connection. A typical example of using this option is updating remote Hosts over the Internet.

## Action menu

Choose what action to perform over the selected remote PCs. The options available in the **Action** menu depend on what you have selected in the **Connection type** field:

Windows NT security:

- **Install/Upgrade host** - install or upgrade the remote Host
- **Uninstall host** - remove the Host from the selected remote PCs
- **Start/restart host** - start or restart the remote Host
- **Stop host** - stop the remote Host service

Remote Utilities security:

- **Upgrade host** - upgrade/update the remote Host
- **Uninstall host** - remove the Host from the selected remote PCs
- **Stop host** - stop the remote Host service

## Specify Host MSI package

You need to select a Host **.msi** file with which to do installation or update. This can be either the vanilla package or your custom package that you have prepared using the **Standard MSI** configuration option.

### **Important!**

If you use the vanilla installer, make sure you download the latest version ([permalink](#)). Likewise, if you use a custom package make sure that you build it on the most recent vanilla package.

## Configure settings button

This button launches the *MSI Configurator* where you can pre-configure the Host before the deployment.

## Process action

Click `Process action` to start whatever action you selected in the `Action` field.

### **Windows XP compatibility:**

If Windows XP is installed on any remote PC on your list, you should disable `Simple File Sharing` in Windows XP. To do that, go to `Control Panel` → `Folder Properties` → `View` and clear the `Simple File Sharing` checkbox.

### **Windows 7/Vista Compatibility:**

It is recommended to turn off UAC (User Access Control) for network connections. In the Windows registry open the key `[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies]` and create a new DWORD value `"LocalAccountTokenFilterPolicy"=dword:00000001`

Skip turning off UAC advice if you install the Host on a domain.
